ABSTRACT

Pituitary hormones play an important role energy expenditure and body temperature regulation during exercise. The aim of the study was to investigate the effect of two different endurance training in ambient temperature (30.76 ± 1.71°C and 57.92 ± 5.80% r.h.) on plasma growth hormone (GH) and prolactin (PRL) levels in non-trained healthy subjects. Twenty-four untrained healthy men participated in an 8-wk progressive two different endurance-training program. Subjects were divided into two groups: an interval running group (IR), and continuous running group (CR). Both groups were performed 3 days/wk. Growth hormone, PRL and VO_{2max} levels were assessed at the beginning and the end of the training period. Body temperature (T_{B}) was also measured at the beginning and immediately after each training. The exercise type affected plasma PRL (8.52 vs. 6.50 ng/ml IR and CR groups, P < 0.02) but did not alter plasma GH levels (0.95 vs 0.63 ng/ml IR and CT groups, P > 0.38). Plasma GH level at the end of training of skeletal muscle. The effect of training on the GH response to acute exercise is uncertain with different results being reported. Possible reasons for these discrepancies are: (i) differences in exercise duration and severity (ii) individual nutritional and hormonal status; (iii) technical differences in assay protocols (iv) adaptation to training. At rest, GH secretion is pulsatile and is influenced by age, gender, nutrition, sleep, body composition, fitness, and sex steroid hormones. During a 24-h period, spontaneous GH secretion is maximal at night in close association with slow wave sleep. Few studies have assessed the effect of period of the day on the GH and cortisol responses to exercise. Two studies reported no effect of period of the day on the GH response to exercise. The pituitary hormone response to such exercise is often described as a ‘stress response’ and, as such, implies a common mechanism for stimulating the release of several different hormones. Most hormones released during exercise are also increased as the result of passive heat exposure and the idea of a role for body temperature in the control of hormone release during exercise has been supported by a number of studies. Prolactin release from the anterior pituitary gland occurs in response to raised core body temperature both as a result of exercise and passive heating. Growth hormone concentrations increase as a result of exercise and the extent is governed by exercise intensity and has been reported to be linearly related to core temperature during exercise. Prolactin release during exercise has been shown to differ in the relationship between prolactin concentration and rectal temperature in hot and cool conditions. The aim of the study was to investigate the effect of two different endurance training in ambient temperature (30.76 ± 1.71°C and 57.92 ± 5.80% r.h.) on plasma growth hormone

(GH) and prolactin (PRL) levels in non-trained healthy subjects.

Materials and Methods

General design

Subjects performed two exercise training period to investigate the effect of different endurance training methods on plasma GH and PRL levels at ambient temperatures of 30 °C and 60% r.h. Blood samples were collected pre and post training periods and T_B were measured before and immediately after each training.

Subjects

Twenty-four (n=12 IR, n=12 CR) untrained healthy university student participated in the study. Their physical characteristics (mean ± SD) were: IR; age, 24.27 ± 2.71 yr; ht, 1.75 ± .06 cm; body mass, 74.5 ± 3.4 kg; VO_2max; 32.45±6.4 ml kg^-1 min^-1 and for CR; age, 22.73±3.51 yr; ht, 1.73 ± .06 cm; body mass, 71.9 ± 2.7 kg; VO_2max; 31.93 ± 4.7 ml kg^-1 min^-1.

Experimental design

IR group was performed interval running. First 2 wk one set that included 250 m, 400 m, 650m ant 900 m running 1min jog between each running distance, from 3^rd wk till 7^th wk two set and last two wk three set at the intensity of 60 - 80% target heart rate. CR group performed running exercise from 25 to 60 minutes for 3 days a wk, at the intensity of 50-70% target heart rate that was calculated by Karvenon method for each subject.

Before the exercise-training program: On the day of a test, subjects arrived at the test area at 08.00 h having fasted from midnight. Each subject participated in two randomized experiments separated by interval or continuously running group. Blood samples were taken for determination of pre-exercise values of hormones than shuttle-running test began to measure of the VO_{2max}.

Body temperature (T_B) measurements: Before and immediately after each training session, the T_B was measured with BRAUN IRT-4520 Thermoscan and recorded. Subjects did not drink water during exercise training.

After the exercise training program: Finally the last measurements were performed and blood samples withdrawn for determination of post-exercise values of hormones than shuttle running test was made to measure of the last VO_{2max}.

Blood analysis

Blood samples were taken from all subjects at rest at the start of the study. Samples were again taken at eight wk at maximal exercise performance. The blood was collected from the antecubital vein into sterile test tubes. The tubes were centrifuged at 4500 rpm for 10 min at 4°C for separation of the serum, which was frozen to -80°C until needed for analysis. Growth hormone and PRL concentrations were measured by using IMMULITE 2000 analyzer with chemiluminescence method (Skybio Ltd, UK).

Statistical Analysis

The effect of endurance trainings on GH, PRL, T_B and VO_{2max} were tested before and after training by 2-way ANOVA using the GLM Procedure (SPSS, ver. 11.5.0, Chicago, IL, USA). The linear model included the effect of training and time relative to training and their interaction. Statistical significance was declared at p<0.05.

Results

In an environment in which the average temperature and humidity ratio are respectively 30.76 ± 1.71°C and 57.92 ± 5.80% r.h., the effects of exercise on the parameters are as follows.

Interval Running Group (IR): The interval endurance training-induced increase of body temperature was higher after training periods and this was significant (P<0,05).

![FIGURE 1](image-url)

PLASMA GH AND PRL LEVELS 8 WK TRAINING PERIOD UNDER HOT ENVIRONMENTS (30.76°C AND 57.92% R.H.). SIGNIFICANT DIFFERENCE IS BEFORE AND AFTER FOR PRL (**P<0.02).
Continuous Running Group (CR): The continuous endurance training-induced increase of T_B was higher after training periods and this was significant (P<0.05).

Discussion

The stresses of physical exertion often are complicated by environmental thermal condition. In the following discussion, we focus on the endocrinology responses to short-term training period in hot environments.

The aim of this investigation was to compare the GH, PRL and cardiovascular responses during different endurance training methods. The present study showed that both endurance training method (interval and continuous) cause an increase at VO2_max. Endurance training was chosen as a model of exercise to observe the developing of VO2_max. Because common goal of this type training method is to increase of VO2_max. This goal was achieved with both methods after the training period.

Growth Hormone: The effects of exercises performed in different environments have been the subject of many researches from past to present. If we take a look at the results of previous studies; Buckler observed that GH increased due to the temperature at 10°C during a treadmill exercise of 20 min. did not show a rise in body temperature during an exercise of intermediate level that was performed at 4°C. Cross-with his collaborators observed that GH decreased and GH increased at 22°C, though there was a rise in the body temperature during an exercise of intermediate level that was performed at 4°C. Cross-with his collaborators demonstrated that, in a 40 minutes of exercise performed with 65% VO2_max, increase in both body temperature and GH was observed at 23°C, however, this increase was observed as 2 times more at 39°C.

Hot environment and exercise result in changes by effecting the hormone regulation of the organism through central nervous system. If the adaptation mechanisms of a person exposed to this situation can demonstrate the necessary concordance. Otherwise, many health related problems arise. For example, Frewin with his collaborators observed that, the rising body temperature at 10°C during a treadmill exercise of 20 min. did not change the GH level; however, the same exercise resulted in an increase of 426% in GH at 40°C.

Exercise intensities effect these changes to a large extent. Raynaud with his collaborators, performed bicycle ergometry exercise at 24°C and 33°C at different intensities (47-59-70%). As a result, increase in GH and T_B was recorded in all exercises with increasing intensity except for the one performed at an intensity of 47%.

The new observations are that while GH release during the first 30–40 min of exercise shows a close relationship with rising rectal temperature, unlike prolactin, this relationship was similar in hot and cool conditions. Wee with his collaborators stated that exercise increased GH release, however Vigas with his collaborators, suggested that the rise in plasma GH levels were not due to exercise, contrarily it might be due to the increased T_B, and Armstrong and Hatfield stated that GH levels might increase due to stress that forms with the increase at the temperature of the environment.

Performed studies are rather related to the reactions given to the acute exercises performed in hot environment. Wheldon stated that swimming exercise at room temperature increased GH level. However, the hormonal response that the body gives due to thermoregulation after a short and long period of exercise is important. In the presented study, a significant rise in GH as a result of stamina exercises at increased pace for 8 wk was not observed. In this case, if GH does not increase though average environmental temperatures and humidity rate’s being 30.76 ± 1.71°C and 57.92 ± 5.80% r.h, respectively, increase in T_B, and increase in exercise intensity, then the most important reason for this is acclimatization. Acclimatization only occurs with regular exercise. With regular exercises performed in hot environment, our body adapts physiologically and decreases the negative effects of temperature.

Secretion of plasma GH depends on different reasons like type of exercise, body temperature and age. In present study, increment in GH level was higher in IR group than that of CR group who trained at same environmental temperature. Ftaiti indicated that exercise done in hot environment was much more effective to increase of GH level. Although Vargas with his collaborators reported that increment in body temperature during exercise triggered GH secretion, in present study, increased body temperature did not did not significantly effect GH level, also the results of the study done by Tamer supported our results.

Prolactin: Previous observations concerning the release of prolactin when exercising in hot and cool environments, indicating that ambient temperature has a major effect in modulating the response. As in GH, PRL also changes due to various reasons. Some of them are the water level and temperature of the body. After exercise with different levels of water given to sportsmen/sportswomen, plasma PRL levels were determined to be at higher values at the 40th and 60th minutes of the exercise. The reason for this increase was attributed to increased body temperature.

Paez with his collaborators found a significant increase in PRL level after a 100 m. free style swimming exercise. Meeusen with his collaborators detected that there was a 14% increase in PRL levels in cyclers who had performed excessive exercise. In another exercise, according to the results of exercise performed in environments of different temperatures, body temperature may be a stimulus for the GH and PRL release. In healthy people kept inside the water at 38-39°C for 25 minutes without exercise, a slight increase in body temperature and GH and decrease in PRL were observed.

The core temperature and PRL responses between the pre and post interval and continuous training period were not correlated. Much investigation has shown that increases in PRL at exhaustion are significantly related to core temperature and ratings of perceived exertion at exhaustion during prolonged exercise in hot conditions.

Within the program, sportsmen performing continuous running were observed to be more exhauste. Our results indicate that release of prolactin plays a role to show exhaustion in the sportsmen.

The level of plasma PRL hormone significantly increased in CR group. As Low with his collaborators claimed that, the reason of increment in PRL hormone level during endurance exercise that is used as a sign in central fatigue could be continuous stimulations sent by central nervous system. Though Burk with his collaborators reported that the maxVO₂ accepted as the other increase PRL hormone level, we can not say same thing for this study because there was no significant difference among maxVO₂ level of both group. Consequently, continuous running can be assumed as the reason of increase in PRL hormone level.

Conclusion

In conclusion, an 8-wk regular exercise result in an increase in plasma PRL level, without altering plasma GH level, which accompanied by elevated body temperature, regardless of the individual’s sporting routine.

Our results show that 8 wk endurance training under hot environment was not the stimulus for growth hormone release. On the other hand, continuously running at same environment was stimulus for prolactin hormone release.
